

## Tutorial Week 03 5COSC001W – Object Oriented Programming – Java

### Exercise 1

### Inheritance

Inheritance allows a class to use the properties and methods of another class. In other words, the derived class inherits the states and behaviors from the base class. The derived class is also called *subclass* and the base class is also known as *super-class*. The derived class can add its own additional variables and methods.

In this first exercise, we want to create a subclass called `Cylinder`, which derived from the superclass `Circle` as showed below:

### Circle Class and Code Reuse

As you can see the class `Circle` is the one that you already implemented in your Tutorial 02. So you can reuse it, just make sure to keep the "Circle.java" file in the same directory and package where the class `Cylinder` will be.

### Cylinder Class

A subclass `Cylinder` is derived from the superclass `Circle`. In the declaration of the class you should use the key word `extends`:

```
public class Cylinder extends Circle{

    //...here the code
```

}

- 1) Implement the class `Cylinder` base on the UML diagram. You can look at the following implementation and try to understand the use of the keyword `super`.

```
public class Cylinder extends Circle {  
    private double height
```

```
    // Constructor with default color, radius and height
```

```
    public Cylinder() {  
        super();  
        height = 1.0;  
    }
```

Call the superclass `Circle`  
constructor with no  
arguments

```
    // Constructor with default radius, color but given height
```

```
    public Cylinder(double height) {  
        super();  
        this.height = height;  
    }
```

Call again the superclass  
`Circle` constructor with no  
arguments

```
    // Constructor with default color, but given radius, height
```

```
    public Cylinder(double radius, double height) {  
        super(radius);  
        this.height = height;  
    }
```

Call the superclass  
constructor `Circle (r)`, since  
there is one parameter

```
    // A public method for retrieving the height
```

```
    public double getHeight() {  
        return height;  
    }
```

```
    // A public method for computing the volume of cylinder
```

```
    // use superclass method getArea() to get the base area
```

```
    public double getVolume() {  
        double volume = getArea()*height;  
        return volume;  
    }
```

```
}
```

- 2) Write a test class to test the class `Cylinder` as follow:

```
public class TestCylinder {
```

```
    public static void main (String[] args) {  
        // Declare and allocate a new instance of cylinder  
        Cylinder c1 = new Cylinder();
```

```
        System.out.println("Cylinder:"  
            + " radius=" + c1.getRadius()  
            + " height=" + c1.getHeight()  
            + " base area=" + c1.getArea()  
            + " volume=" + c1.getVolume());
```

```
        // Declare and allocate a new instance of cylinder, specifying Height  
        Cylinder c2 = new Cylinder(5.0);
```

```
        System.out.println("Cylinder:"  
            + " radius=" + c2.getRadius()  
            + " height=" + c2.getHeight()  
            + " base area=" + c2.getArea()  
            + " volume=" + c2.getVolume());
```

```
        // Declare and allocate a new instance of cylinder specifying radius and height  
        Cylinder c3 = new Cylinder(5.0, 10.0);
```

```

        System.out.println("Cylinder:"
            + " radius=" + c3.getRadius()
            + " height=" + c3.getHeight()
            + " base area=" + c3.getArea()
            + " volume=" + c3.getVolume());
    }
}

```

## Overriding

Overriding means to provide a specific implementation of a method that is already provided by one of its superclasses or parent classes.

- 3) The subclass Cylinder inherits the methods of the class Circle. If the method `getArea()` is called by Cylinder instance it will compute the base area of a cylinder, not the surface area (because is the one implemented in Circle).

In this exercise you have to override the `getArea()` method in the class Cylinder so that it will calculate the surface area of the cylinder. (Remember that the surface area of a cylinder is  $= 2 \pi \times \text{radius} \times \text{height} + 2 \times \text{base-area}$ ).

- 4) In your main create an instance of the class Circle and one of the class Cylinder and call the method `getArea()` from both instances and print the results you get on the screen.

- 5) After overriding the method `getArea()`, does the method `getVolume()` work correctly?

`getVolume()` uses the overridden `getArea()` found in the same class. In fact, Java will search in the superclass only if it cannot find the method in the base class.

How to fix it?

In order to use the `getArea()` method from the superclass you can call `super.getArea()`

- 6) Override in Cylinder the method `toString` inherited from the superclass Circle.

Example:

```

// in Cylinder class
@Override
public String toString() {
    return "Cylinder: subclass of " + super.toString()
        + " height=" + height;
}

```

It uses the method  
`toString()` from the  
superclass Circle

Note: `@Override` is known as annotation (introduced in JDK 1.5). It is optional, but it is quite helpful. What it does is asking to the compiler to check whether there is such a method in the superclass to be overridden. This helps greatly in case of misspelling: e.g. if `@Override` is not used and `toString()` is misspelled as `ToSting()`, it will be treated as a new method in the subclass, instead of overriding the superclass. If `@Override` is used, the compiler will signal an error.

## Exercise 2

According on what you learnt so far let's write a SchoolApplication. This class will have a superclass `Person` and using inheritance you will implement two subclasses, `Student` and `Teacher`.

A `Teacher` will be like `Person` but will have additional properties such as `salary` (the amount the teacher earns) and `subject` (e.g. "Computer Science", "Chemistry", "English", "Other").

A `Student` will be like a `Person` but will have additional properties such as `fee` (the amount the student pays every year), the `grade` and `IDnumber`.

The inheritance hierarchy should appear as follow:

This is the code for the class `Person`:

```
public class Person {  
  
    protected String myName ;    // name of the person  
    protected int myAge;         // person's age  
    protected String myGender;   // "M" for male, "F" for female  
  
    public Person(String name, int age, String gender) {  
        myName = name; myAge = age ; myGender = gender;    }  
    }  
    public String toString() {  
        return myName + ", age: " + myAge + ", gender: " +myGender;  
    }  
}
```

7) Add methods to "set" and "get" the instance variables in the `Person` class. These would consist of: `getName`, `getAge`, `getGender`, `setName`, `setAge`, and `setGender`.

8) Write a `Student` class that extends the parent class `Person`. The class should have:

- Three *instance variables*. They represent the `IDNumber` (`int`), the `fee`(`double`), the `grade` (`int`).
- One *constructor* to initialize name, age, gender, `idNum`. Use the super reference to use the constructor in the `Person` superclass to initialize the inherited values.
- Write "setter" and "getter" methods for all of the class variables. For the `Student` class they would be: `getIDNum`, `getFee`, `setGrade`, and `setIDNum`, `setFee`, `setGrade`.
- Write the `toString()` method for the `Student` class. Use a super reference to do the things already done by the superclass.

9) Write a `Teacher` class that extends the parent class `Person`. The class should have:

- Two *instance variables*. They represent the `salary` (`double`), the `subject`(`string`).

- One *constructor* to initialise name, age, subject, salary. Use the super reference to use the constructor in the Person superclass to initialize the inherited values.
- Write “setter” and “getter” methods for all of the class variables. For the Teacher class they would be: getSalary, getSubject, setSalary, and setSubject.
- Write the toString() method for the Teacher class. Use a super reference to do the things already done by the superclass.

10) Write a testing class with a main() that constructs all of the classes (Person, Student, Teacher) and calls their toString() method. Sample usage would be:

```
Person jack = new Person("Jack Brooke", 27, "M");
System.out.println(jack);

Student beth = new Student("Elisabeth Smith", 16, "F", "122233");
System.out.println(beth);

Teacher sam = new Teacher("Sam Hamilton", 34, "M", "Computer Science",
50000);|
System.out.println(sam);
```

11) Try the following and proof which statements is correct:

```
Person p = new Teacher ("Sam Hamilton", 34, "M", "Computer Science", 50000);
Teacher t = new Person ("Sam Hamilton", 34, "M", "Computer Science", 50000);
Person s = new Student ("Elisabeth Smith", 16, "F", "122233");
```
